Introduction

world- and self-learning interact during operant conditioning

Did language evolve using an ancestral self-learning mechanism?

Method: The TARGET system

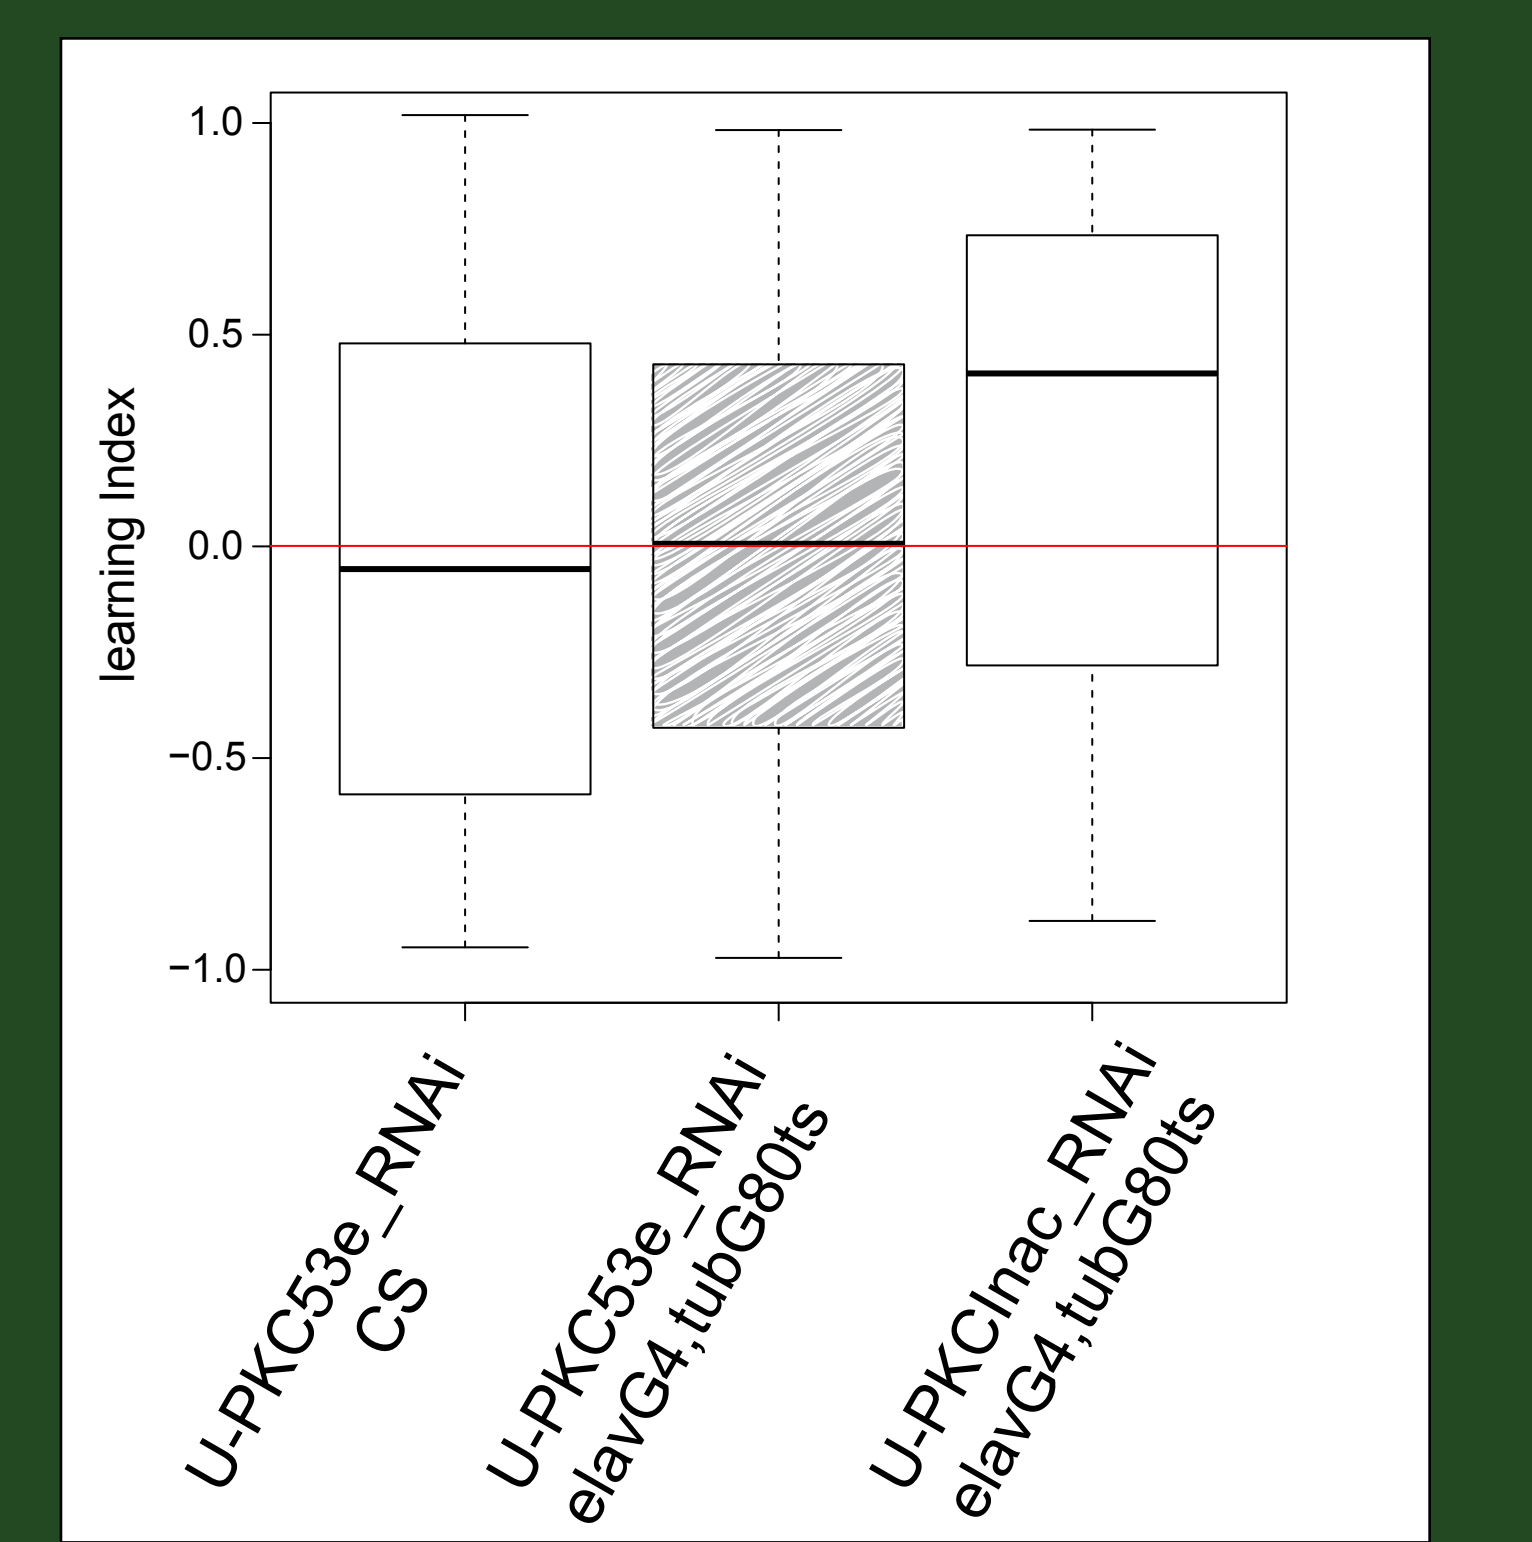

Results 1: PKC53e as a candidate

Putative mutants

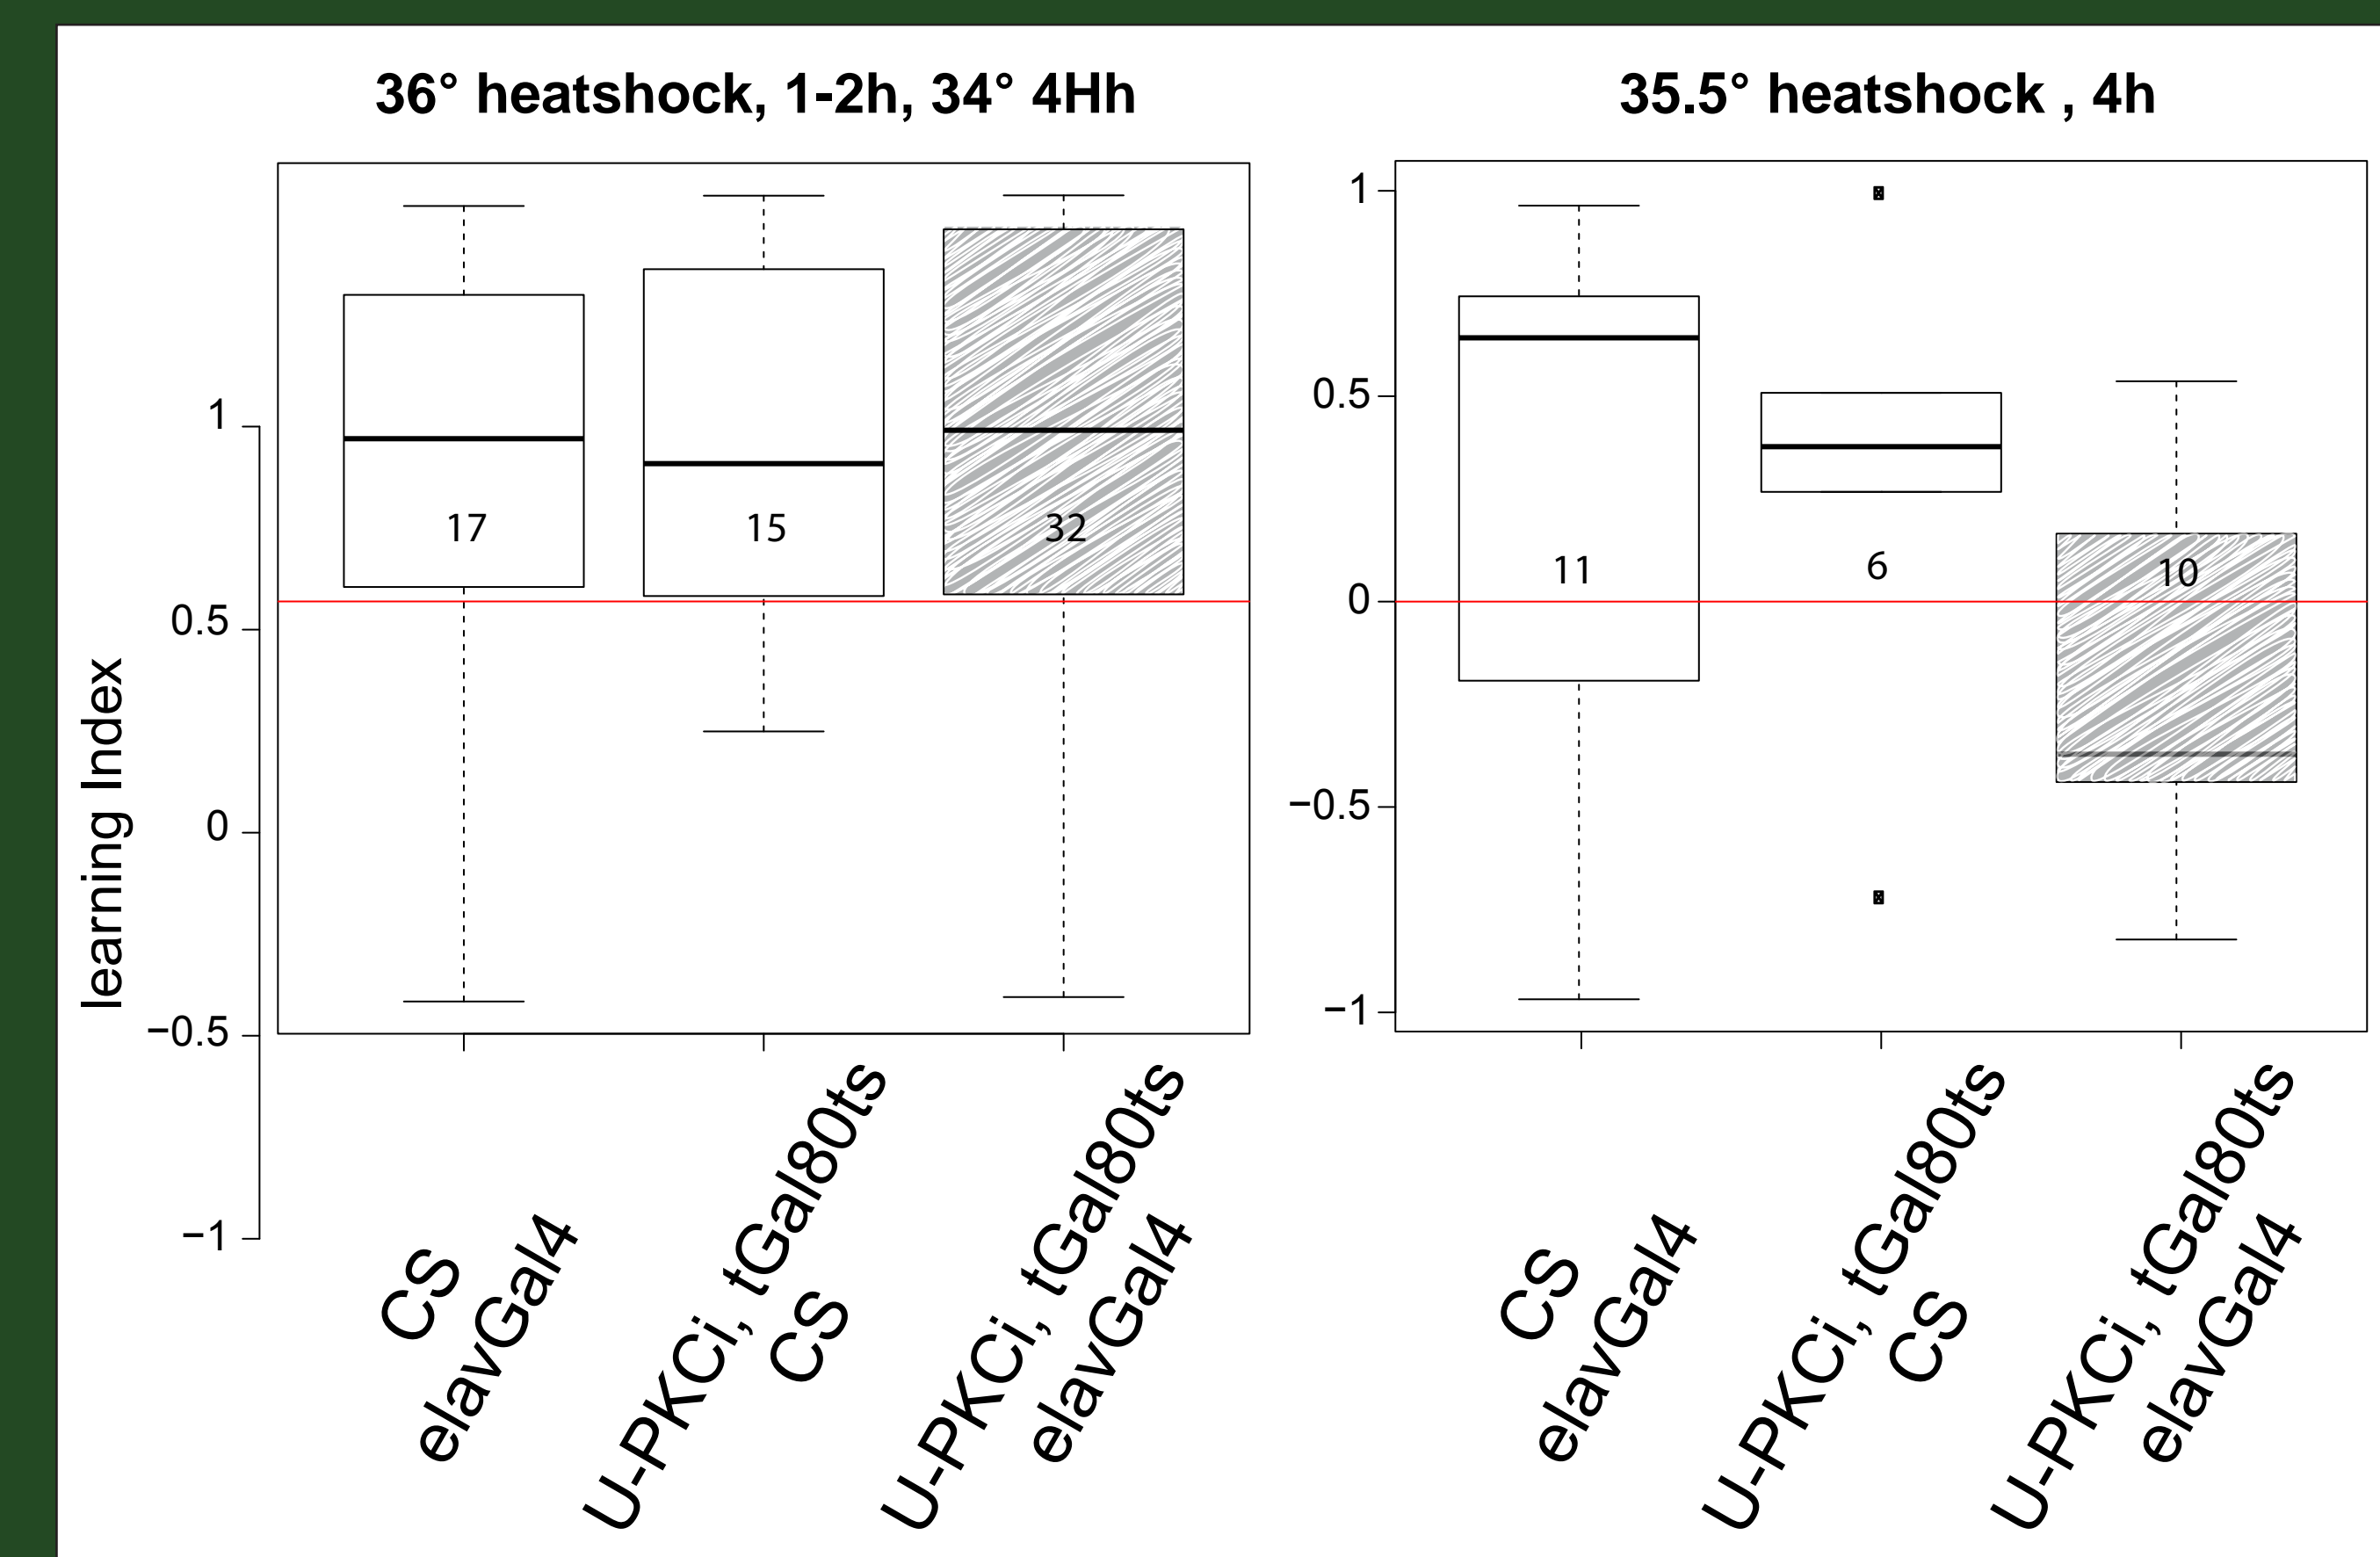

RNAi using TARGET

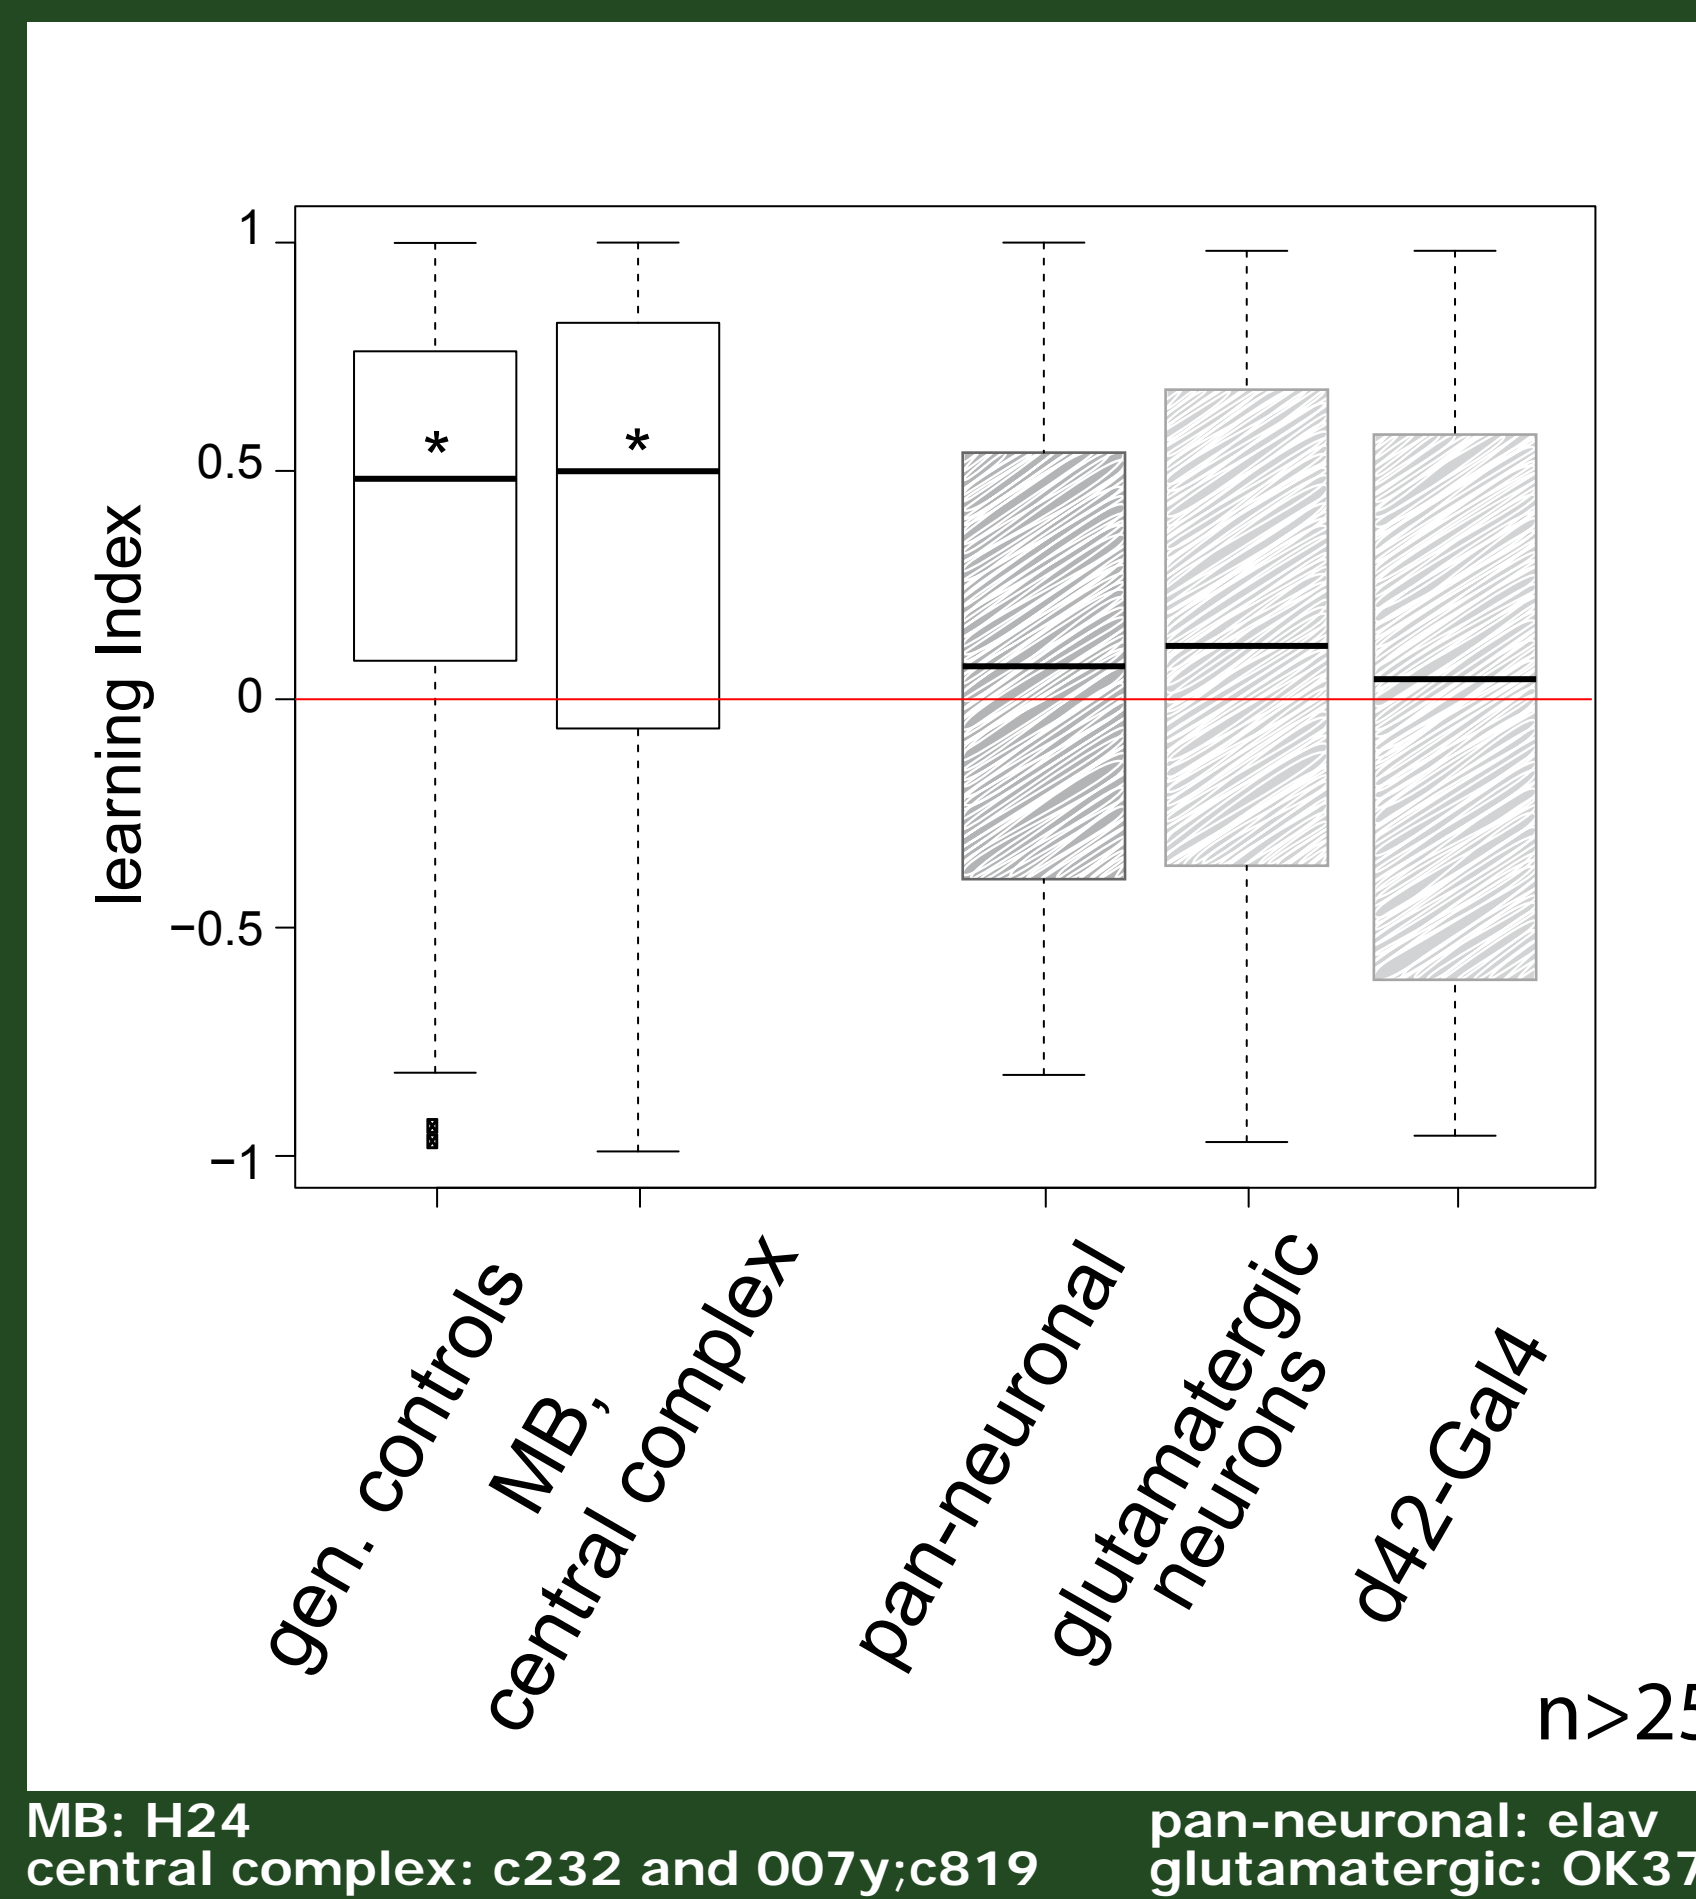

Results 2: Localization of PKC action to glutamatergic neurons

finding a working heat shock protocol:
tub-Gal80ts;UAS-PKCi x elav-Gal4 lines

Candidate screen

motorneuron line
tub-Gal80ts;UAS-PKCi x c380-Gal4, chaGal80

Conclusions

Using an inhibitory peptide of Protein Kinase C (PKCi) we have been able to discover a novel learning mechanism underlying operant self-learning. This mechanism appears to be conserved in the bilaterian clade and also involves the *Drosophila* orthologue of the human 'language gene' FOXP2, *dFoxP*. Experiments using the TARGET system to temporally restrict RNAi expression to adulthood yielded PKC53e as the putative PKC isoform involved in self-learning. Spatially restricting PKCi expression with the TARGET system revealed that PKC activity is required in glutamatergic neurons. Data are currently ambiguous if motorneurons are the responsible glutamatergic subpopulation and further, potentially disambiguating studies are currently ongoing.
